

South West Land Division

Monthly rainfall, temperature and streamflow

Month: AUGUST

Rainfall and streamflow 2026

Rainfall

Rainfall in August was average or below in the South West corner, and average to well above average in the Eastern Wheatbelt. Year-to-date rainfall (January to August) was mostly below to well below average in the South West Corner, and average to above average elsewhere (Map 1). Katanning recorded its lowest year-to-date rainfall on record.

Classifications compared to the 1975 to 2025 base period

Map 1: Rainfall deciles* for January to August 2026 compared to 1975-2025 for the SWLD

* A rainfall decile is a way to show how the amount of rain for a particular place and period compares to the historical record. At each location, rainfall totals for the same calendar period from 1975–2025 are ranked from lowest to highest and divided into ten equal groups (deciles). Decile 1 contains the lowest 10 per cent of rainfalls and decile 10 contains the highest 10 per cent of rainfalls. Rainfall deciles are grouped to represent well below average rainfall to well above average rainfall. The coloured circles in the map show where the 2026 rainfall ranks in these groups.

Streamflow

Mostly below average or lower rainfall conditions across the SWLD from January to August this year have resulted in below average to well below average streamflow across the region. So far this year, the Hotham and Swan rivers have recorded their lowest streamflow on record, while Kalgan River had average flows and the Lort River recorded above average streamflow.

Classifications compared to the 1975 to 2025 base period

Map 2 Streamflow deciles[†] for January to August 2026 compared to 1975-2025 for the SWLD

[†] A streamflow decile is a way to show how the amount of water flowing in a stream, river or other channel for a particular place and period compares to the historical record. At each location, streamflow totals for the same calendar period from 1975–2025 are ranked from lowest to highest and divided into ten equal groups (deciles). Decile 1 contains the lowest 10 per cent of streamflows and decile 10 contains the highest 10 per cent of streamflows. Streamflow deciles are grouped to represent well below average streamflow to well above average streamflow. The coloured circles in the map show where the 2026 streamflow ranks in these groups.

Temperature 2026

The mean maximum temperature in August was above average to very much above average for the SWLD (Bureau of Meteorology [Monthly maximum temperature decile for Western Australia](#)), ranging from 15 to 21 degrees (Map 3).

Future - Seasonal forecast

To complement 2026 tracking for the SWLD, we also consider the rainfall and temperature forecasts, produced by the Bureau of Meteorology. When considering forecasts, it is important to look at the forecast and the forecast model's accuracy. Model accuracy is a measure of how well model forecasts match observed records as they become available.

Maps 4 and 5 below show the temperature and rainfall forecasts for Australia using Bureau of Meteorology modelling, while maps 6 and 7 show the modelling accuracy of these forecasts.

As at 27 August 2026:

- The Bureau of Meteorology expects warm conditions to continue, with an over 80 per cent chance of exceeding the median maximum temperatures for the SWLD from September to November (Map 4).
- The accuracy of the temperature forecast is between 75 and 100 per cent in the SWLD. This indicates a high level of confidence in the forecast (Map 6).
- The rainfall forecast indicates dry conditions for the September to November period with a 20 to 35 per cent chance of exceeding median rainfall across most of south-west corner, and 50 to 60 per cent chance of exceeding median rainfall in inland eastern areas (Map 5).
- The accuracy of the rainfall forecast is moderate to very high (greater than 55 per cent) across most of the SWLD. Forecast accuracy is low for the inland eastern areas (45 to 55 per cent) (Map 7).¹

Bureau of Meteorology tracks global climate indicators to help understand long-term weather patterns. The indicators show an El Nino is underway in the tropical Pacific, with potential for a positive Indian Ocean Dipole to form in winter-spring. Combined, these climate drivers are likely to reduce winter rainfall and bring higher temperatures across the SWLD.

Climate context

Rainfall decline in south-west WA has been greater than anywhere else in Australia. Almost all climate projections indicate a warmer and drier future for the region, marking it as a global hotspot for reduced rain because of climate change.

Since the 1970s, in south-western WA there has been:

- a 16 per cent decline in April–October rainfall¹
- about 80 per cent less flow into Perth’s water supply dams²
- up to 70 per cent less recharge to groundwater.³

Climate change poses significant challenges for communities in WA that are experiencing more extreme weather events such as tropical storms, floods and bushfires. The State Government is supporting businesses, communities and local governments to understand the future climate and adapt to the impacts of climate change.

The [Climate Science Initiative](#) will produce the most detailed and comprehensive Western Australian climate change projections to date, extending to the year 2100.
